

CS 305 Computer Networks

Chapter 3 Transport Layer (I)

Jin Zhang

Department of Computer Science and Engineering
Southern University of Science and Technology

Chapter 3: Transport Layer

our goals:

- ❖ understand principles behind transport layer services:
 - multiplexing, demultiplexing
 - reliable data transfer
 - flow control
 - congestion control
- ❖ learn about Internet transport layer protocols:
 - UDP: connectionless transport
 - TCP: connection-oriented reliable transport
 - TCP congestion control

Chapter 3 outline

3.1 transport-layer services

3.2 multiplexing and demultiplexing

3.3 connectionless transport: UDP

3.4 principles of reliable data transfer

3.5 connection-oriented transport: TCP

- segment structure
- reliable data transfer
- flow control
- connection management

3.6 principles of congestion control

3.7 TCP congestion control

Transport services and protocols

- ❖ provide *logical communication* between app processes running on different hosts
- ❖ transport protocols run in end systems
 - send side: breaks app messages into *segments*, passes to network layer
 - rcv side: reassembles segments into messages, passes to app layer
- ❖ more than one transport protocol available to apps
 - Internet: TCP and UDP

Transport vs. network layer

- ❖ *network layer*: logical communication between hosts
- ❖ *transport layer*: logical communication between processes
 - relies on, enhances, network layer services

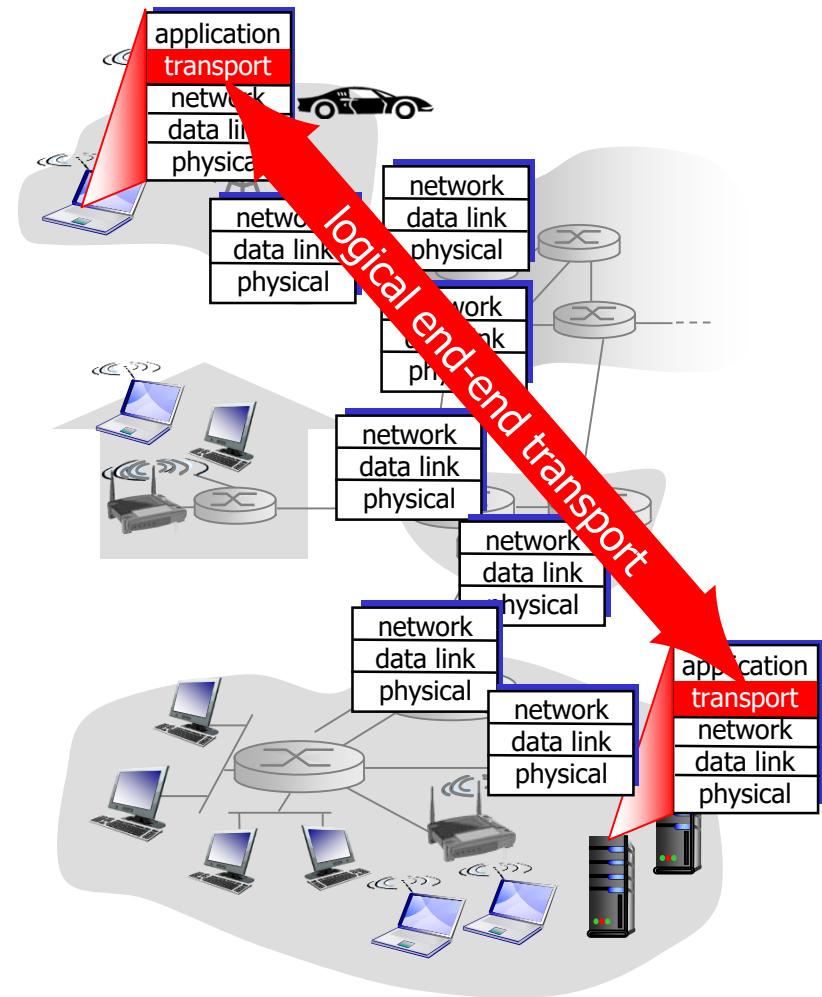

household analogy:

12 kids in Ann's house sending letters to 12 kids in Bill's house:

- ❖ hosts = houses
- ❖ processes = kids
- ❖ app messages = letters in envelopes
- ❖ transport protocol = Ann and Bill who demux to in-house siblings
- ❖ network-layer protocol = postal service

Internet transport-layer protocols

- ❖ reliable, in-order delivery (TCP)
 - congestion control
 - flow control
 - connection setup
- ❖ unreliable, unordered delivery: UDP
 - no-frills extension of “best-effort” IP
- ❖ services not available:
 - delay guarantees
 - bandwidth guarantees

Chapter 3 outline

3.1 transport-layer services

3.2 multiplexing and demultiplexing

3.3 connectionless transport: UDP

3.4 principles of reliable data transfer

3.5 connection-oriented transport: TCP

- segment structure
- reliable data transfer
- flow control
- connection management

3.6 principles of congestion control

3.7 TCP congestion control

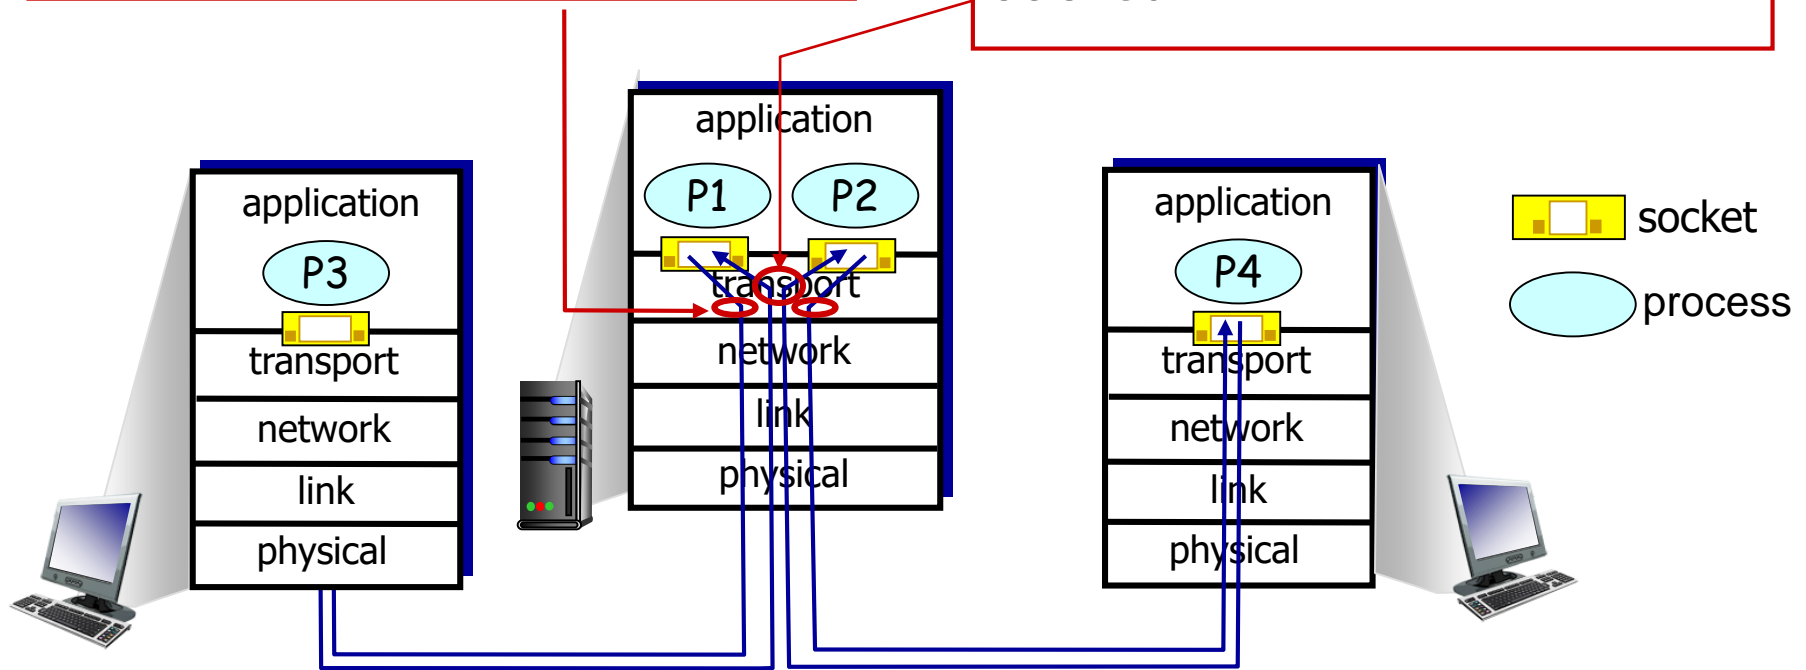

Multiplexing/demultiplexing

multiplexing at sender:

handle data from multiple sockets, add transport header (later used for demultiplexing)

demultiplexing at receiver:

use header info to deliver received segments to correct socket

How demultiplexing works

- ❖ host receives IP datagrams from network layer
 - each datagram has source IP address, destination IP address
 - each datagram carries one transport-layer segment
 - each segment has source, destination port number
- ❖ host uses *IP addresses & port numbers* to direct segment to appropriate socket

TCP/UDP segment format

Connectionless demultiplexing

- ❖ *recall*: created socket has host-local port #:

```
clientSocket =  
socket(AF_INET, SOCK_DGRAM)  
clientSocket.bind(('', 19157))
```

- ❖ *recall*: when creating datagram to send into UDP socket, must specify
 - destination IP address
 - destination port #

- ❖ when host receives UDP segment:

- checks destination port # in segment
- directs UDP segment to socket with that port #

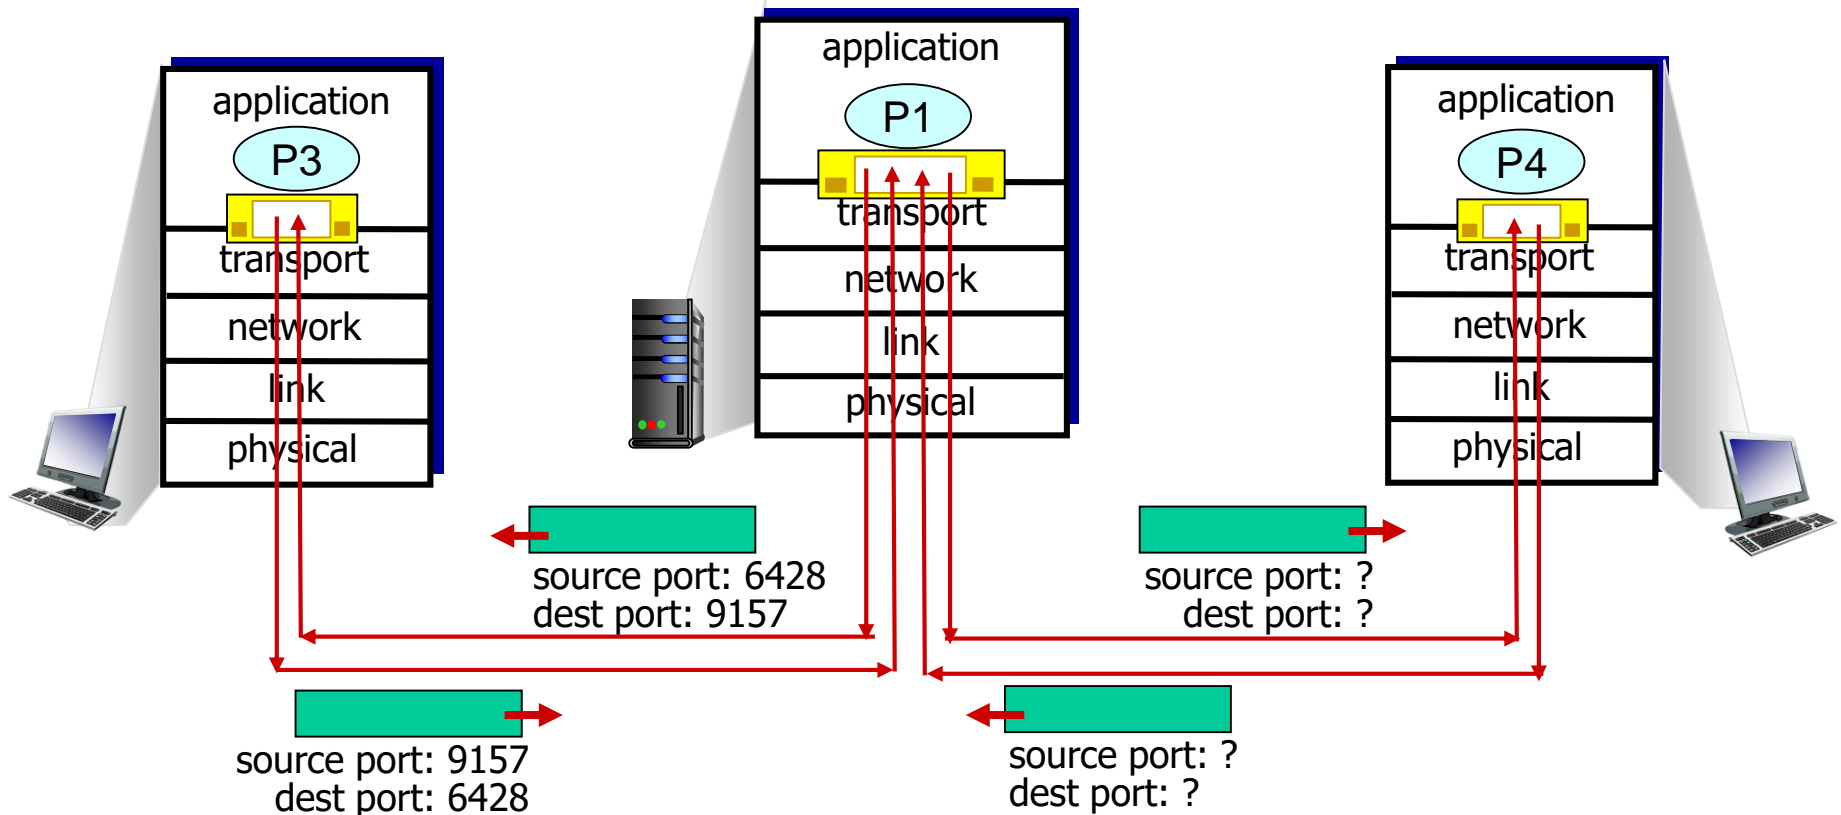

IP datagrams with *same dest. port #*, but different source IP addresses and/or source port numbers will be directed to *same socket* at dest

Connectionless demux: example

```
mysocket2 =  
    socket(AF_INET,  
          SOCK_DGRAM)  
mysocket2.bind  
    ((' ', 9157))
```

```
serversocket =  
    socket(AF_INET,  
          SOCK_DGRAM)  
serversocket.bind  
    ((' ', 6428))
```

```
mysocket1 =  
    socket(AF_INET,  
          SOCK_DGRAM)  
mysocket1.bind  
    ((' ', 5775))
```

Connection-oriented demux

- ❖ Server **create a welcome socket** with port no. 12000

```
serversocket = socket(AF_INET, SOCK_STREAM)  
serversocket.bind(('', 12000))
```
- ❖ Client **connect to the server**, the request is a TCP segment with a flag bit = 1

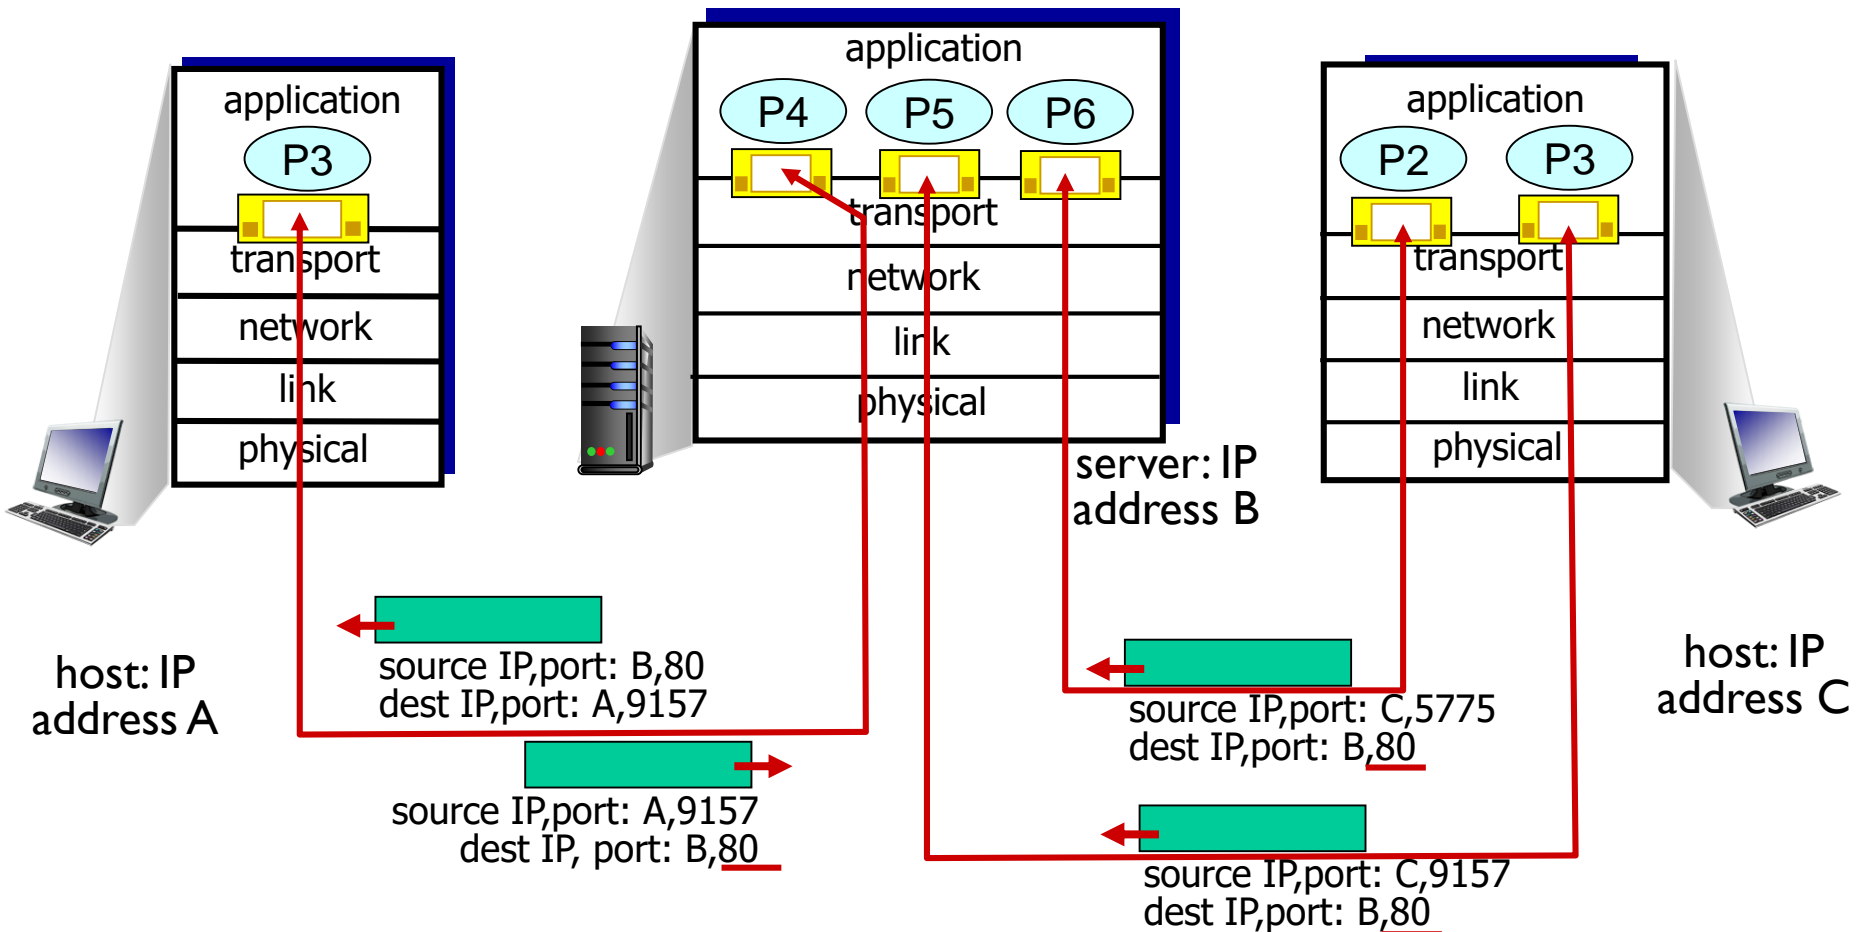

```
clientsocket = socket(AF_INET, SOCK_STREAM)  
clientsocket.connect((ServerName, 12000))
```
- ❖ Server **create a new socket** to accept the connection

```
connectionsocket, addr = serversocket.accept()
```
- ❖ All the packets sent to the server with the corresponding (source IP, source port, dest IP, dest port) will be demuxed to the connectionsocket

Connection-oriented demux

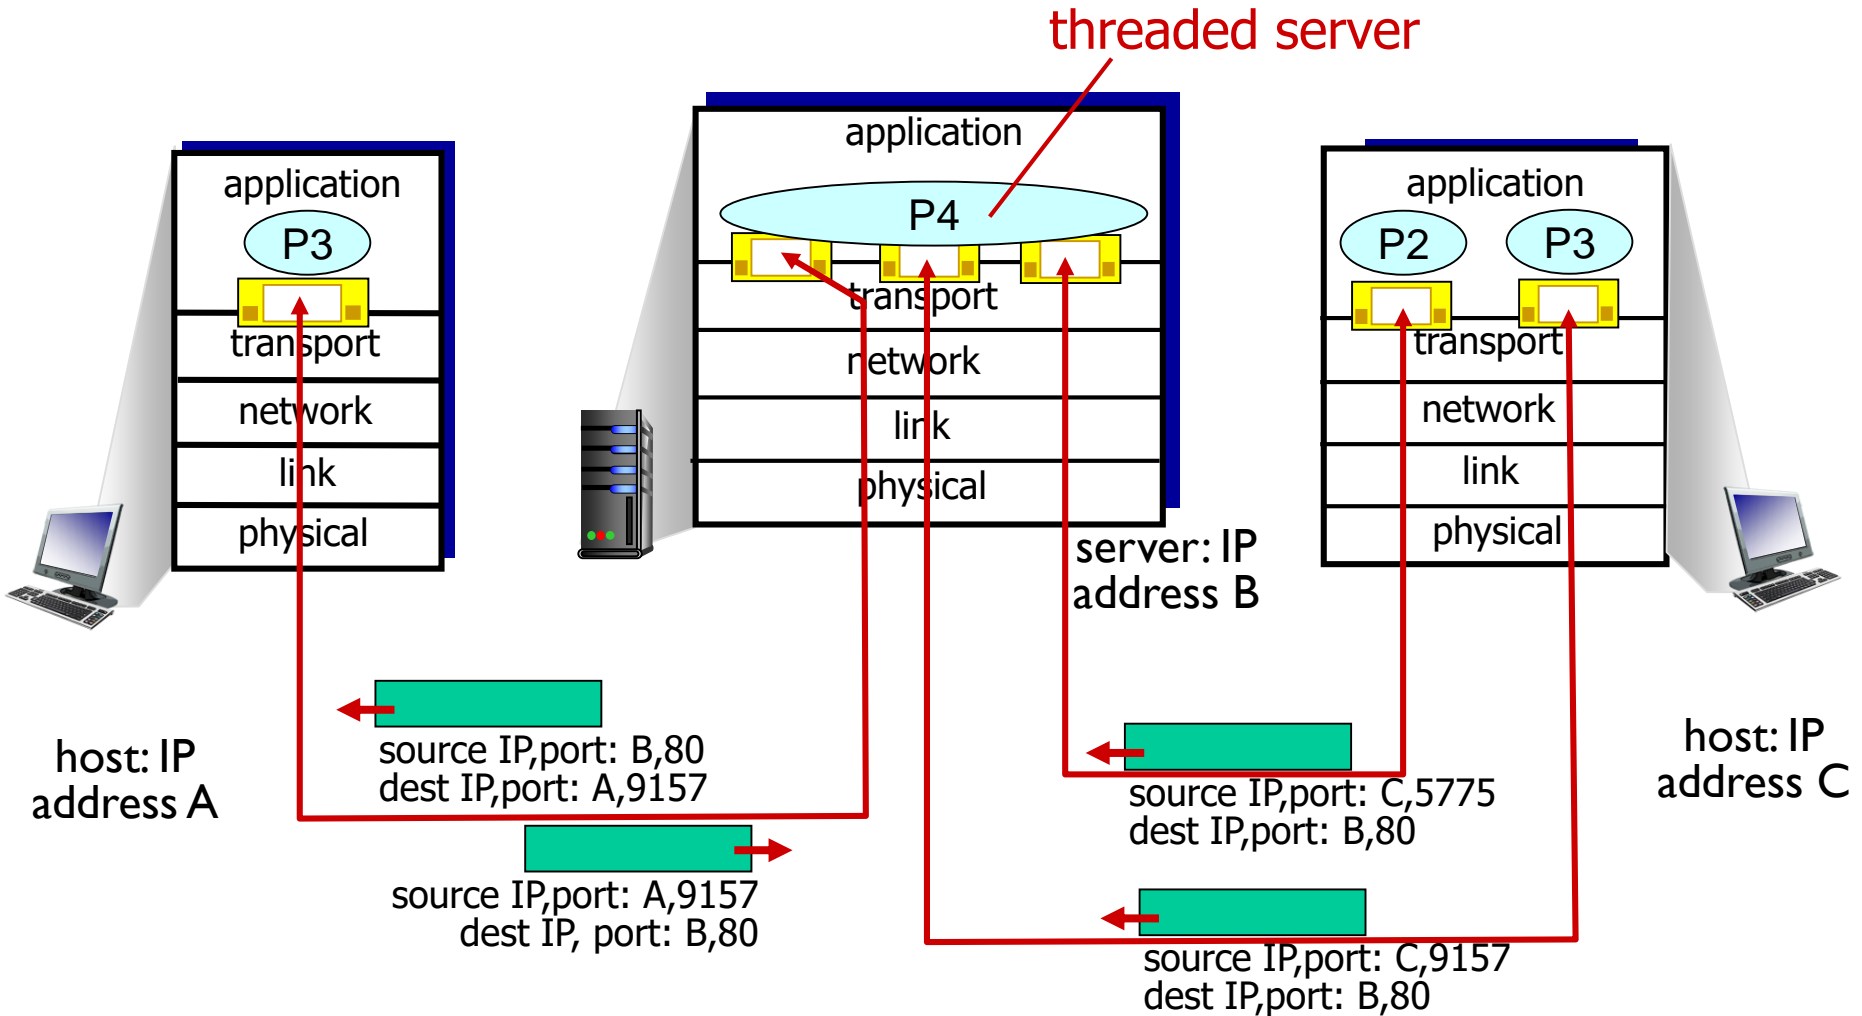

- ❖ TCP socket identified by 4-tuple:
 - source IP address
 - source port number
 - dest IP address
 - dest port number
- ❖ demux: receiver uses all four values to direct segment to appropriate socket
- ❖ server host may support many simultaneous TCP sockets:
 - each socket identified by its own 4-tuple
- ❖ web servers have different sockets for each connecting client
 - non-persistent HTTP will have different socket for each request

Connection-oriented demux: example

three segments, all destined to IP address: B,
dest port: 80 are demultiplexed to *different* sockets

Connection-oriented demux: example

Chapter 3 outline

3.1 transport-layer services

3.2 multiplexing and demultiplexing

3.3 connectionless transport: UDP

3.4 principles of reliable data transfer

3.5 connection-oriented transport: TCP

- segment structure
- reliable data transfer
- flow control
- connection management

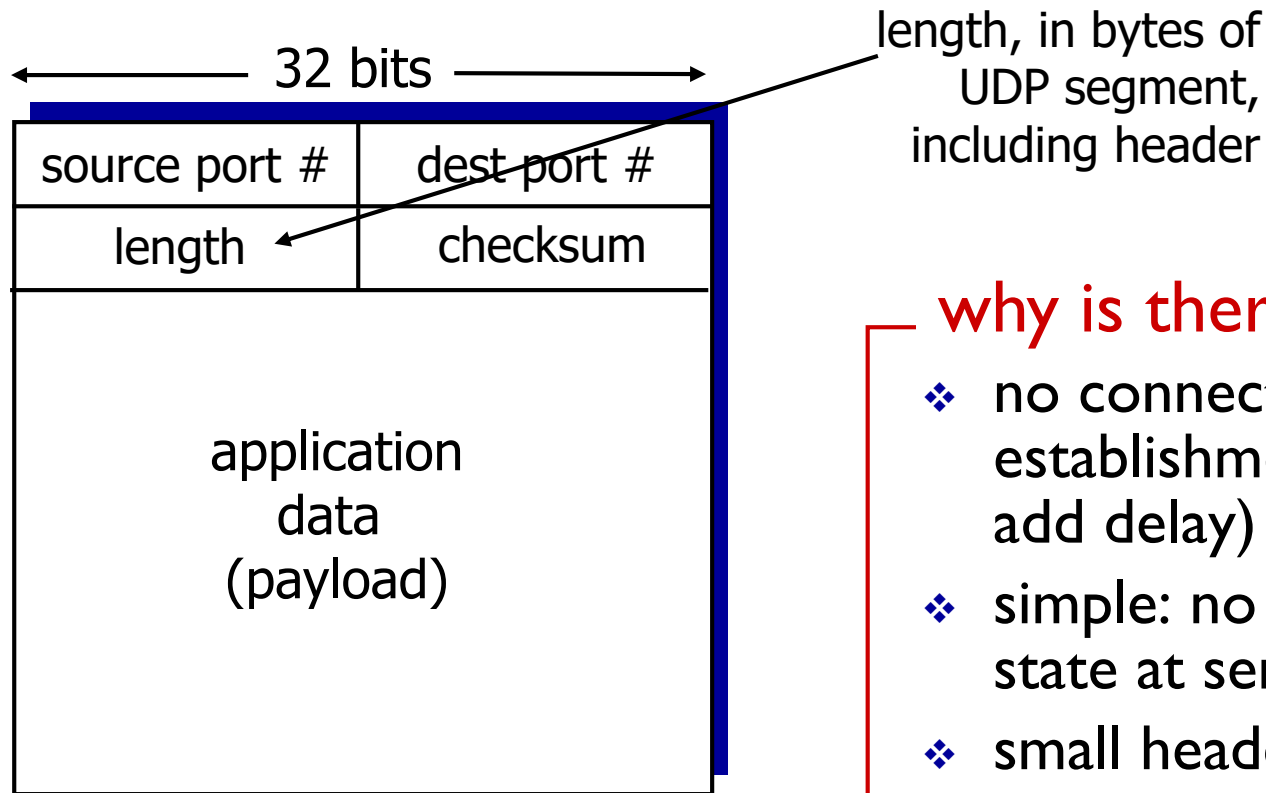

3.6 principles of congestion control

3.7 TCP congestion control

UDP: User Datagram Protocol [RFC 768]

- ❖ “no frills,” “bare bones”
Internet transport
protocol
- ❖ “best effort” service,
UDP segments may be:
 - lost
 - delivered out-of-order
to app
- ❖ *connectionless*:
 - no handshaking
between UDP sender,
receiver
 - each UDP segment
handled independently
of others
- ❖ UDP is used in:
 - streaming multimedia
apps (loss tolerant, rate
sensitive)
 - DNS
 - SNMP
- ❖ reliable transfer over
UDP:
 - add reliability at
application layer
 - application-specific error
recovery!

UDP: segment header

UDP segment format

why is there a UDP?

- ❖ no connection establishment (which can add delay)
- ❖ simple: no connection state at sender, receiver
- ❖ small header size
- ❖ no congestion control: UDP can blast away as fast as desired

UDP checksum

Goal: detect “errors” (e.g., flipped bits) in transmitted segment

sender:

- ❖ treat segment contents, including header fields, as sequence of 16-bit integers
- ❖ checksum: addition (one's complement sum) of segment contents
- ❖ sender puts checksum value into UDP checksum field

receiver:

- ❖ compute checksum of received segment
- ❖ check if computed checksum equals checksum field value:
 - NO - error detected
 - YES - no error detected.
But maybe errors nonetheless? More later
....

Internet checksum: example

example: add two 16-bit integers

	1	1	1	0	0	1	1	0	0	1	1	0	0	1	1	0
	1	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1
<hr/>																
wraparound	1	1	0	1	1	1	0	1	1	1	0	1	1	1	0	1
<hr/>																
sum	1	0	1	1	1	0	1	1	1	0	1	1	1	1	0	0
checksum	0	1	0	0	0	1	0	0	0	1	0	0	0	0	1	1

Note: when adding numbers, a carryout from the most significant bit needs to be added to the result

Chapter 3 outline

3.1 transport-layer services

3.2 multiplexing and demultiplexing

3.3 connectionless transport: UDP

3.4 principles of reliable data transfer

3.5 connection-oriented transport: TCP

- segment structure
- reliable data transfer
- flow control
- connection management

3.6 principles of congestion control

3.7 TCP congestion control

UDP Transfer: rdt is not needed

- ❖ UDP cannot guarantee reliable data transfer
- ❖ But, it's faster!

TCP Transfer: rdt is needed

- ❖ TCP can guarantee reliable data transfer
- ❖ But, it's slower and more complex!

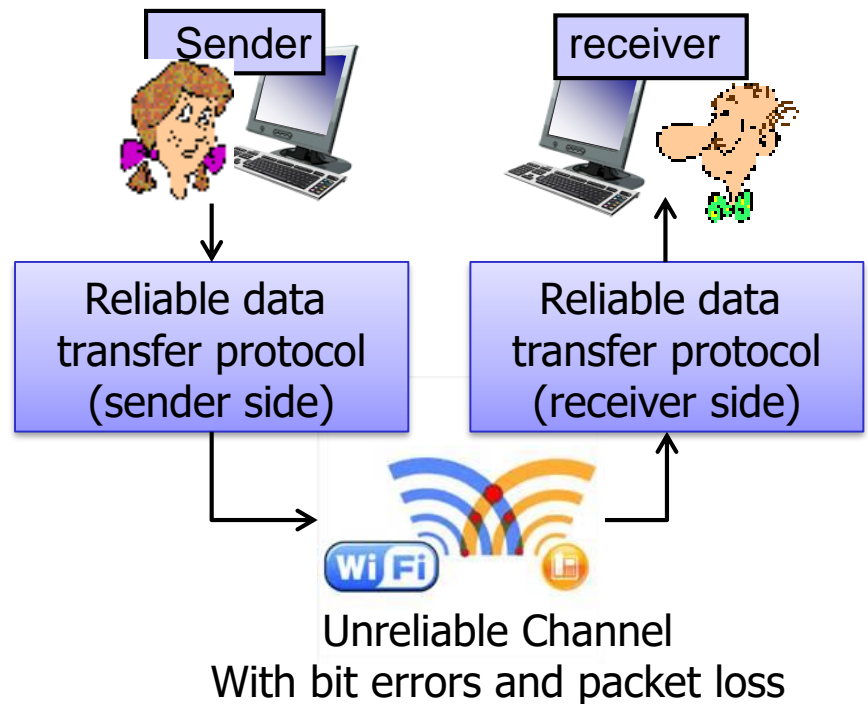

Reliable Data Transfer (rdt)

- ❖ In top-10 list of important networking topics!
- ❖ Characteristics of **unreliable channel** will determine complexity of rdt protocol

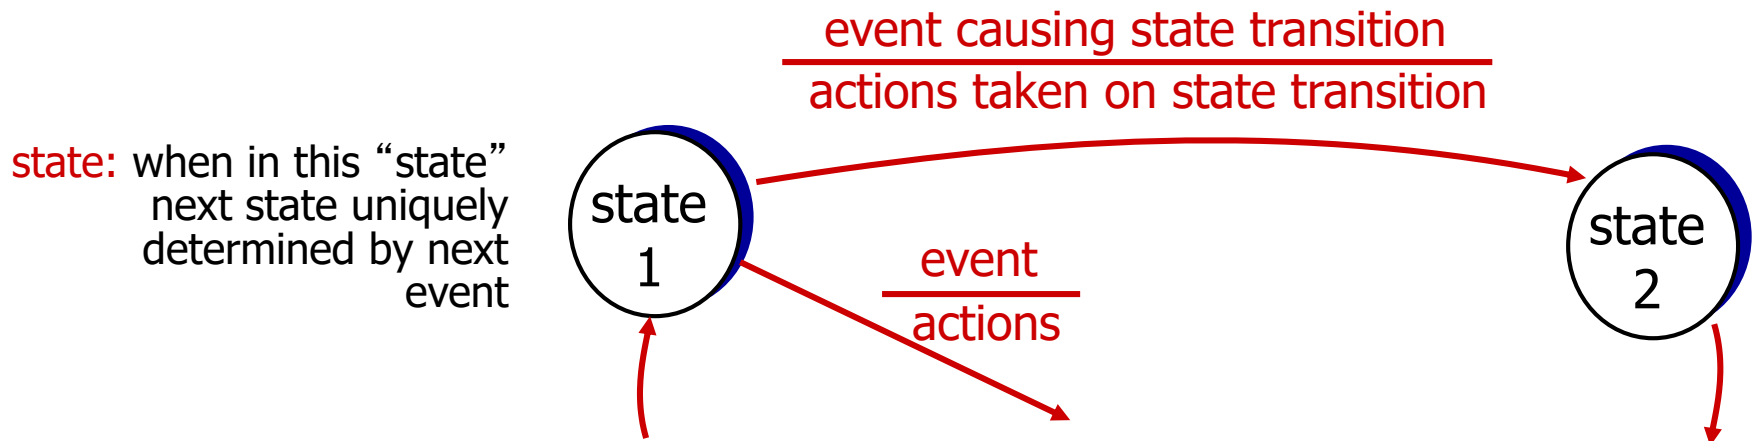

Reliable Channel

Reliable data transfer: getting started

We' ll:

- ❖ **Incrementally** develop sender, receiver sides of **reliable data transfer protocol (rdt)**
- ❖ Consider only **unidirectional data transfer**
 - but control info will flow on both directions!
- ❖ Use finite state machines (FSM) to specify sender, receiver

rdt1.0: reliable transfer over a reliable channel

❖ Underlying channel **perfectly reliable**

- no bit errors
- no loss of packets

❖ Rdt 1.0:

- sender sends data into underlying channel
- receiver reads data from underlying channel

sender

receiver

rdt2.0: channel with bit errors

- ❖ Underlying channel may **flip bits** ($0 \rightarrow 1$) in packet
- ❖ *The question*: how to recover from errors?

*How do humans recover from “errors”
during conversation?*

rdt2.0: channel with bit errors

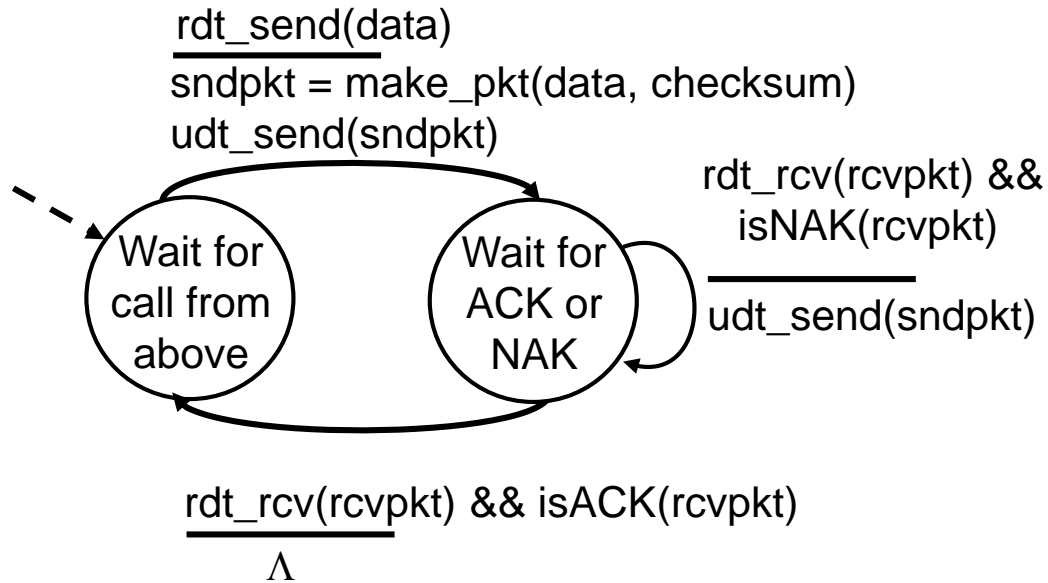

- ❖ Underlying channel may **flip bits** ($0 \rightarrow 1$) in packet
- ❖ **The question**: how to recover from errors?

rdt2.0: channel with bit errors

- ❖ Two key mechanisms:
 - **error detection**
 - **feedback**: control msgs (ACK, NAK) from receiver to sender
- ❖ Error detection: checksum
- ❖ Feedback messages:
 - **acknowledgements (ACKs)**: receiver explicitly tells sender that pkt received OK
 - **negative acknowledgements (NAKs)**: receiver explicitly tells sender that pkt had errors
 - sender retransmits pkt on receipt of NAK

rdt2.0: FSM specification

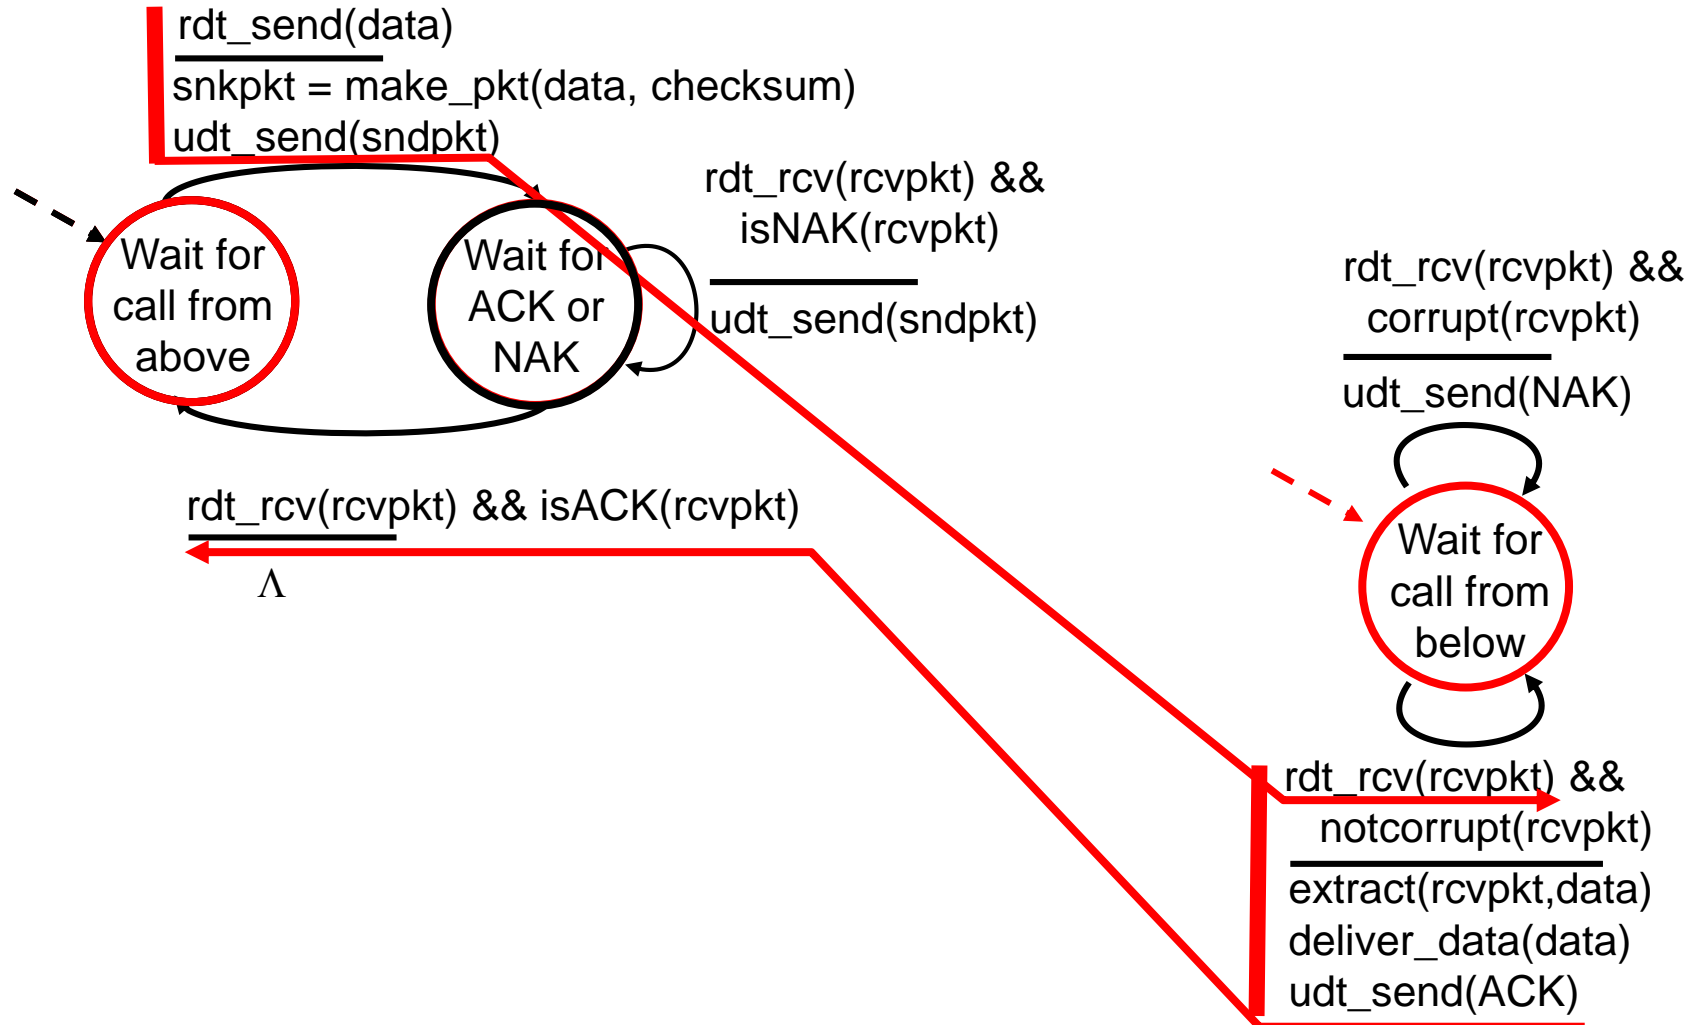

sender

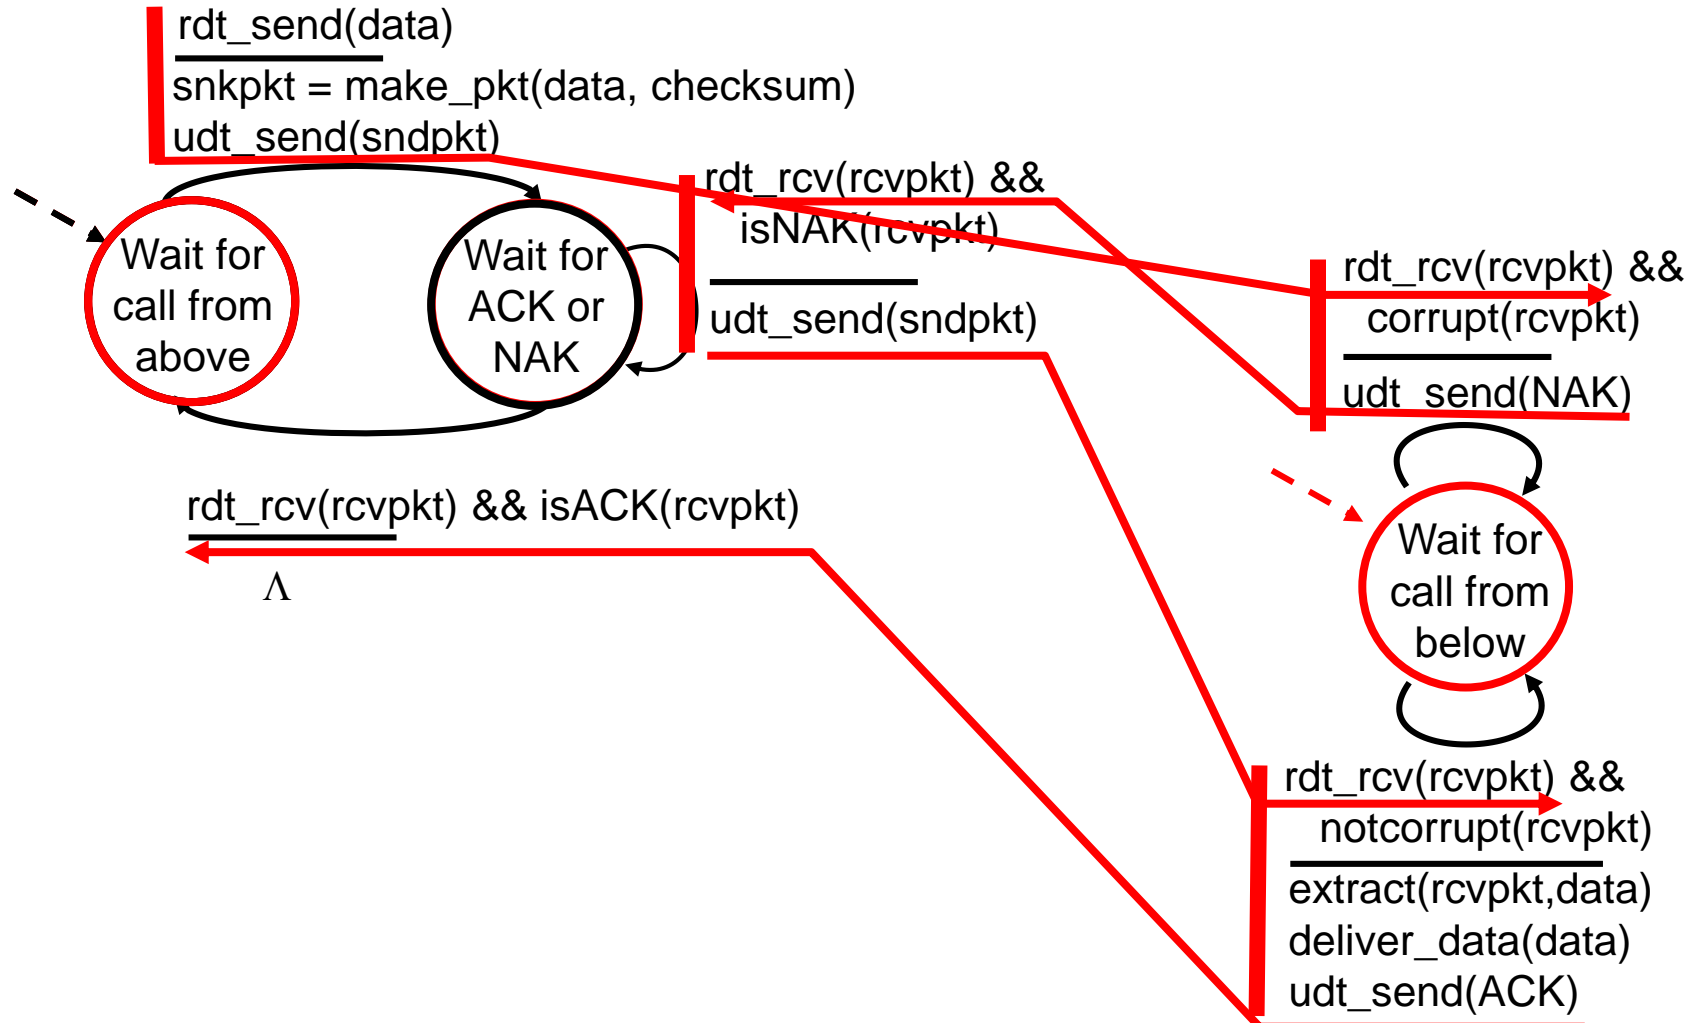

receiver

rdt2.0: operation with no errors

rdt2.0: error scenario

rdt2.0 has a fatal flaw!

what happens if ACK/NAK corrupted?

- ❖ sender doesn't know what happened at receiver!
- ❖ can't just retransmit: possible duplicate

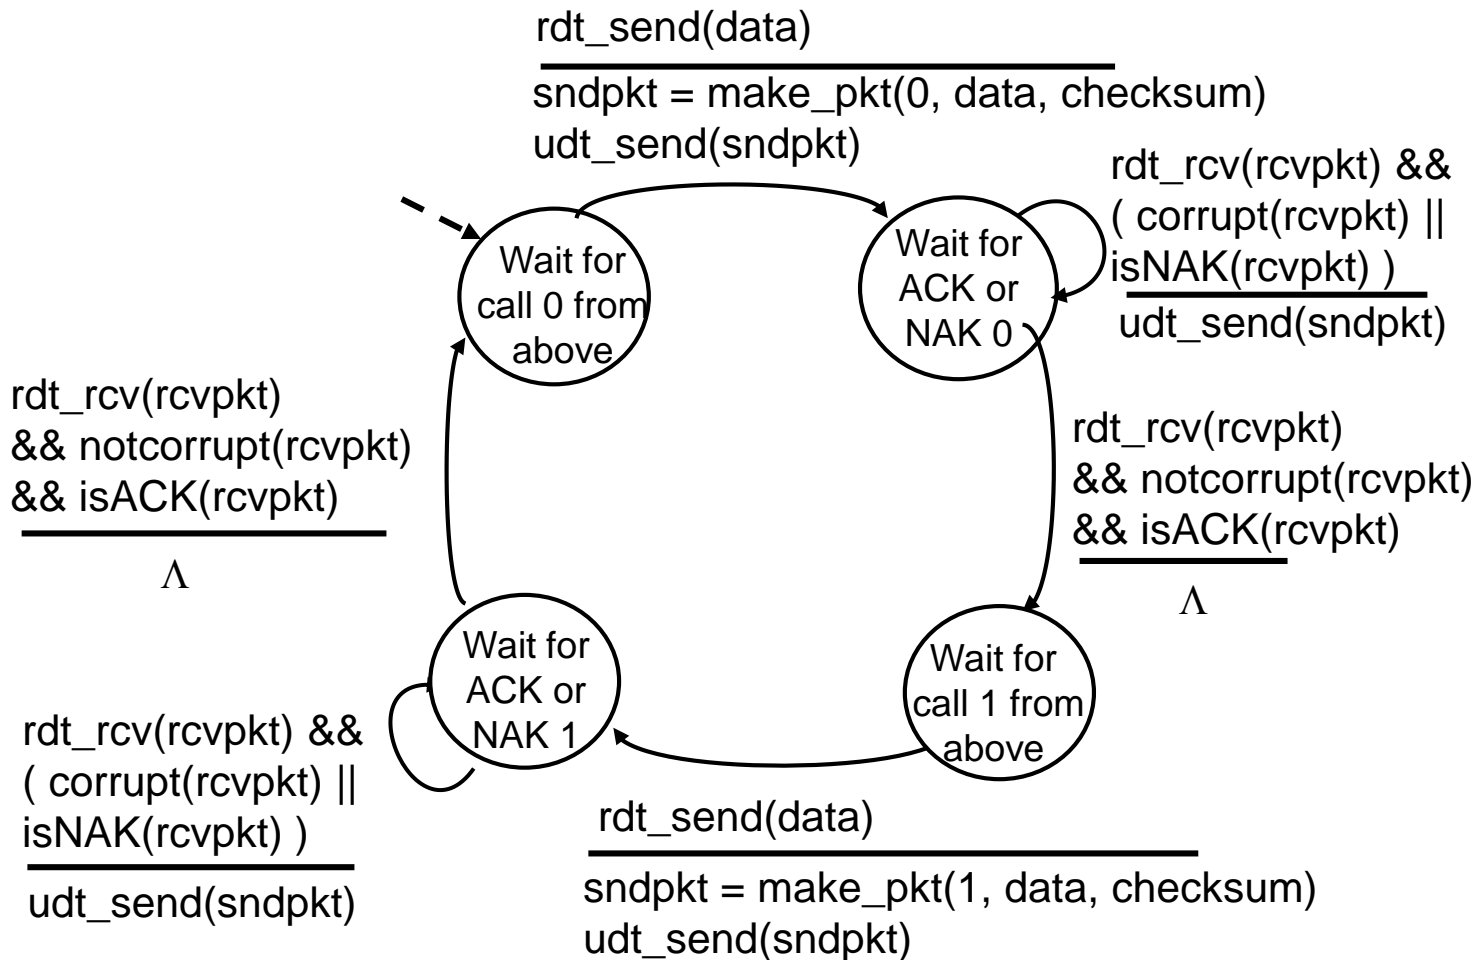

handling duplicates:

- ❖ sender retransmits current pkt if ACK/NAK corrupted
- ❖ sender adds *sequence number* to each pkt
- ❖ receiver discards (doesn't deliver up) duplicate pkt

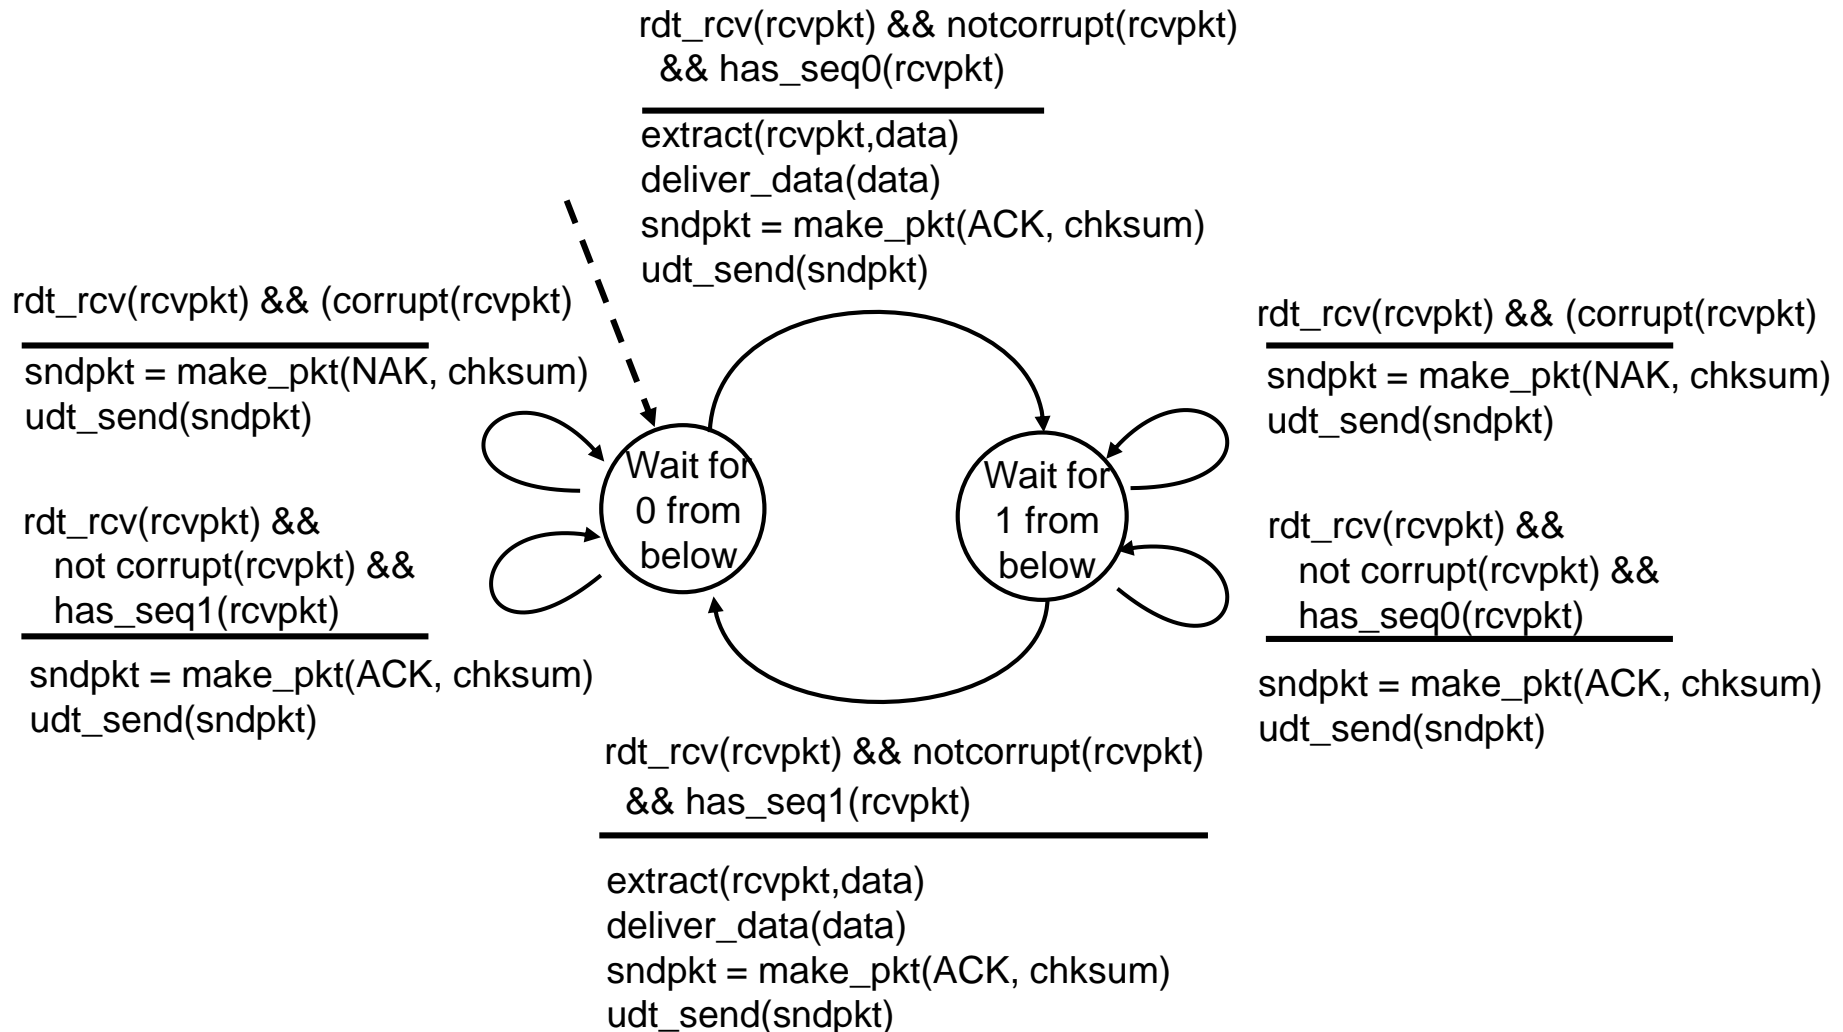

stop and wait

sender sends one packet,
then waits for receiver
response

rdt2.1: sender, handles garbled ACK/NAKs

rdt2.1: receiver, handles garbled ACK/NAKs

rdt2.1: discussion

sender:

- ❖ seq # added to pkt
- ❖ two seq. #'s (0,1) will suffice. Why?
- ❖ must check if received ACK/NAK corrupted
- ❖ twice as many states
 - state must “remember” whether “expected” pkt should have seq # of 0 or 1

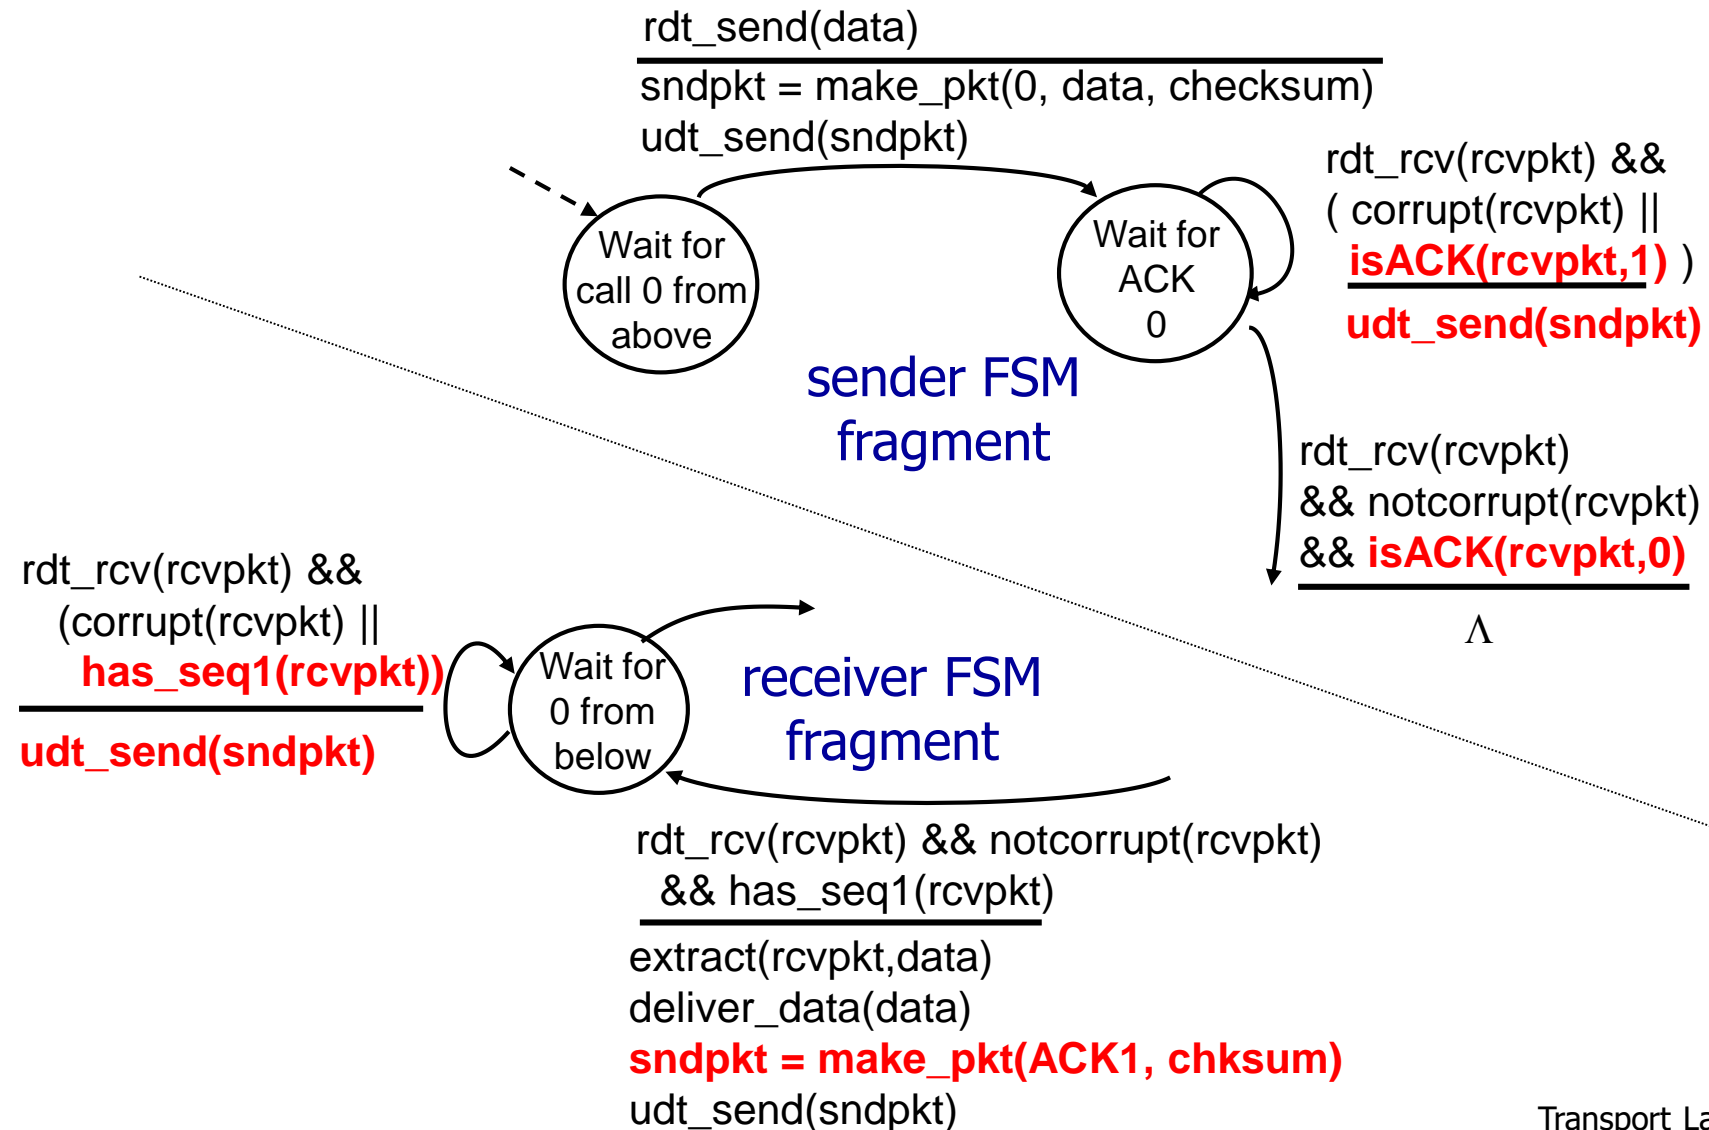

receiver:

- ❖ must check if received packet is duplicate
 - state indicates whether 0 or 1 is expected pkt seq #
- ❖ note: receiver can *not* know if its last ACK/NAK received OK at sender

rdt2.2: a NAK-free protocol

- ❖ same functionality as rdt2.1, using ACKs only
- ❖ instead of NAK, receiver sends ACK for last pkt received OK
 - receiver must *explicitly* include seq # of pkt being ACKed
- ❖ duplicate ACK at sender results in same action as NAK: *retransmit current pkt*

rdt2.2: sender, receiver fragments

rdt3.0: channels with errors *and* loss

new assumption:

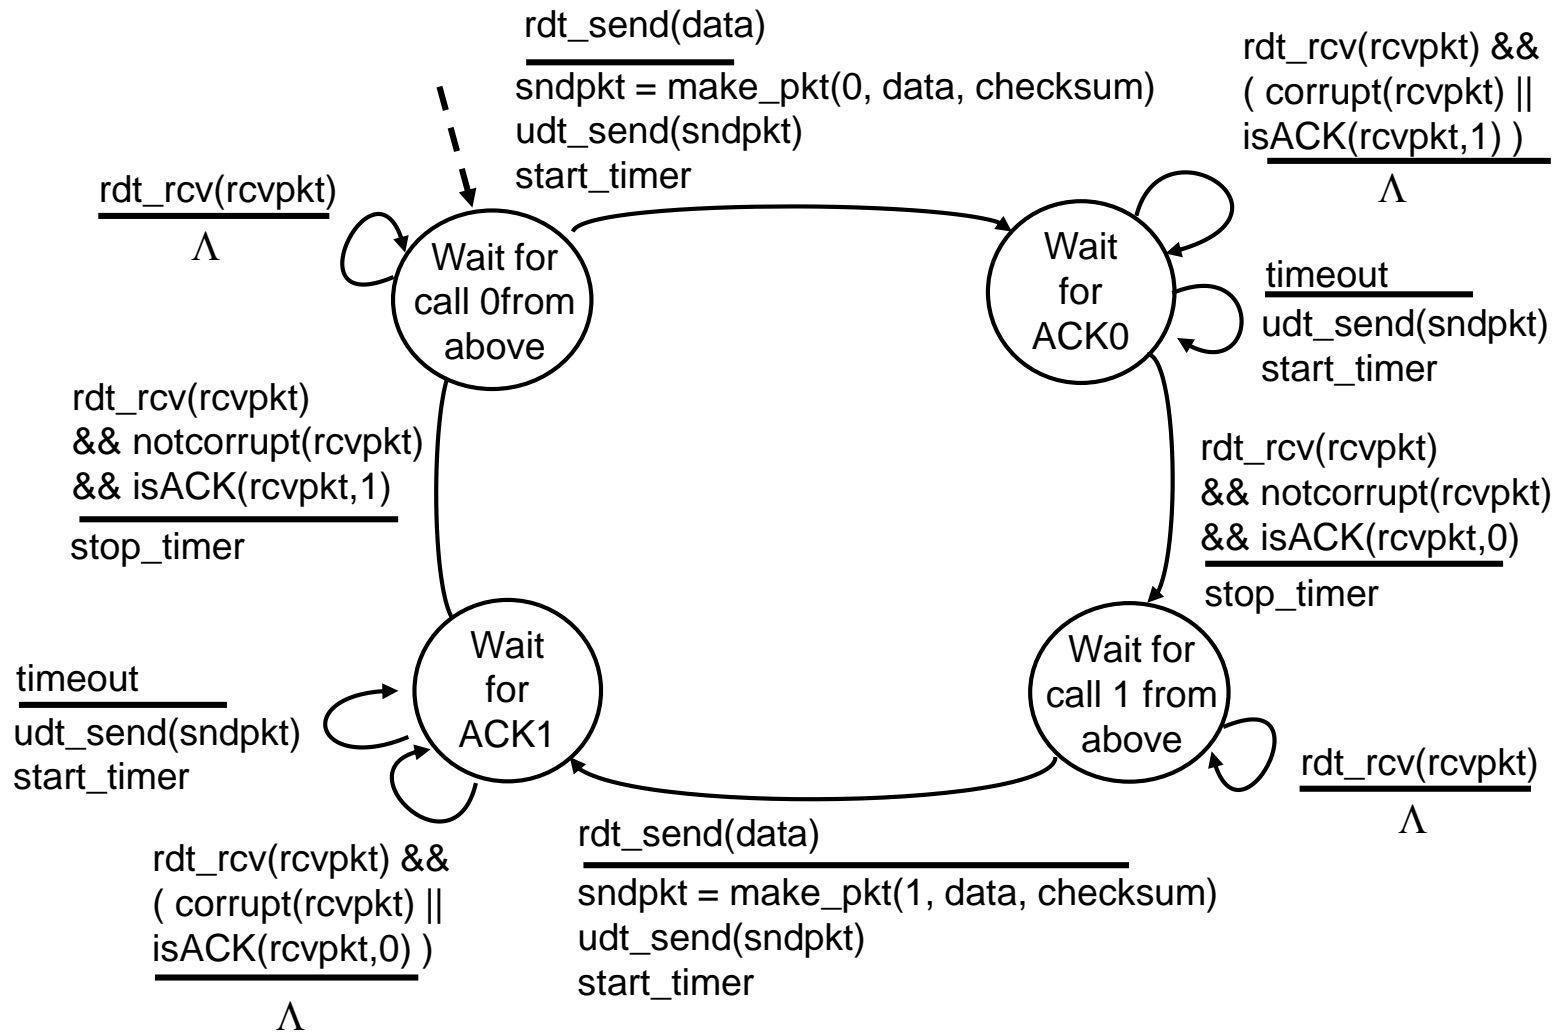

underlying channel can also lose packets (data, ACKs)

- checksum, seq. #, ACKs, retransmissions will be of help ... but not enough

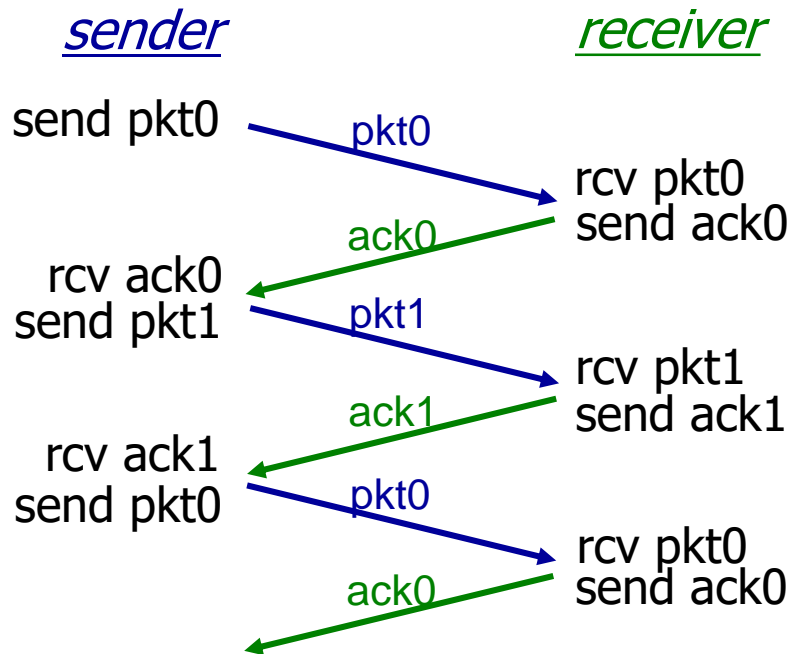

approach: sender waits “reasonable” amount of time for ACK

- ❖ retransmits if no ACK received in this time
- ❖ if pkt (or ACK) just delayed (not lost):
 - retransmission will be duplicate, but seq. #'s already handles this
 - receiver must specify seq # of pkt being ACKed
- ❖ requires countdown timer

rdt3.0 sender

rdt3.0 in action

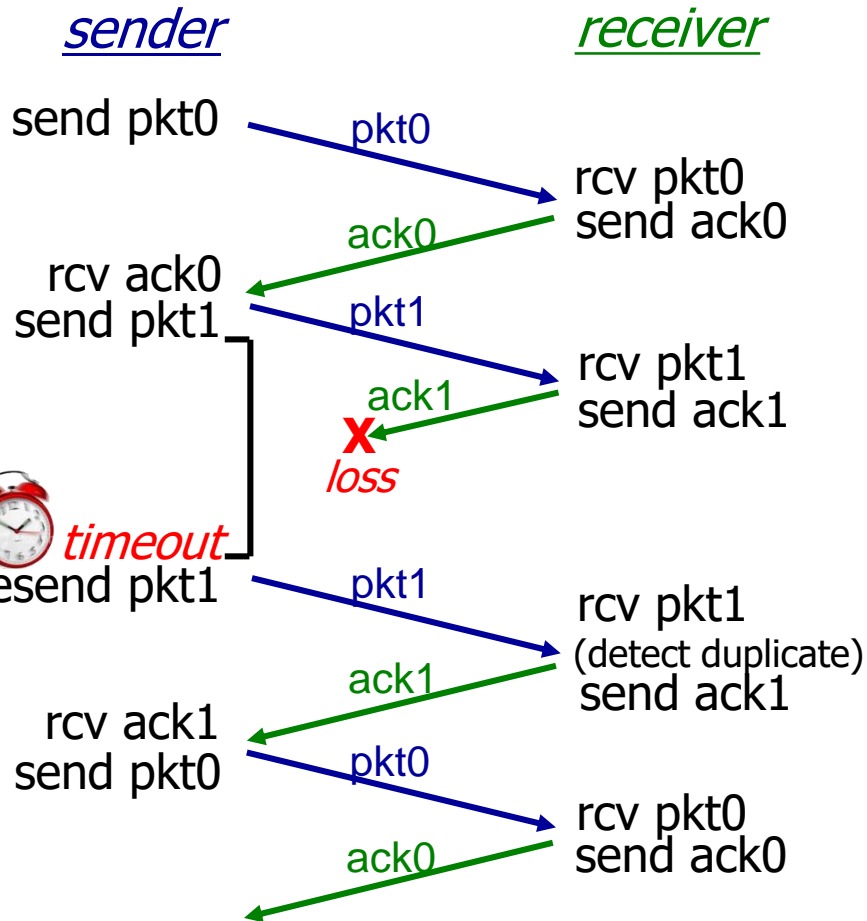

(a) no loss

(b) packet loss

rdt3.0 in action

(c) ACK loss

(d) premature timeout/ delayed ACK
